Q1. A unix node has a total of 7 pointers. The first 4 pointers are **direct block pointers**, the 5th one is a **single indirect**, 6th is a **second indirect** and 7th node is another **Second indirect pointer**. Considering each data block is 2kb. What's the max size of a file in your file system? [3]

Q2. assume you have a directory structure where you are trying to go to this path: **“root / quiz / q3.txt”** where the **“q3.txt” file has 1 data block written already**. Now, you are appending on the existing file and **adding another block**. Consider that I have already performed the **open(root / quiz / q3.txt)** for you. Design the access path flow for this write() operation only: [6]

Data Bitmap	Inode Bitmap	root inode	quiz inode	q3 inode	root data	quiz data	q3 data[0]	q3 Data[1]

Q3. Write True/False only: [1]

- In a free file management data bitmap, the sum of the bitmap represents the total free blocks.
- Superblock of the file system is the first thing OS runs in order to retrieve the file system information.
