Q1. A unix node has a total of 6 pointers. The first 3 pointers are **direct block pointers**, the 4th one is a **single indirect**, 5th is a **second indirect** and 6th node is another **Second indirect pointer**. Considering each data block is 2kb. What's the max size of a file in your file system? [3]

Q2. assume you have a directory structure where you are trying to go to this path: **“root / cse/ prac.txt”** where the **“prac.txt”** file has **1 data block written already**. Now, you are appending on the existing file and **adding another block**. Consider that I have already performed the **open(root / quiz / q3.txt)** for you. Design the access path flow for this write() operation only: [6]

Data Bitmap	Inode Bitmap	root inode	cse inode	prac inode	root data	cse data	prac data[0]	prac Data[1]

Q3. Write True/False only: [1]

- 1 data block is directly mapped into 1 sector of the HDD
- The total number of unique files that can be made depends on the size of the block.
